 **UtahState**University
COLLEGE OF ENGINEERING

 THE
UNIVERSITY
OF UTAH

Petascale??

- Discussion starter: who among us uses HPC for hydrologic modeling?
- We don't even do terascale!
- We do single CPU gigascale modeling.
- High Performance Computing is a new frontier.

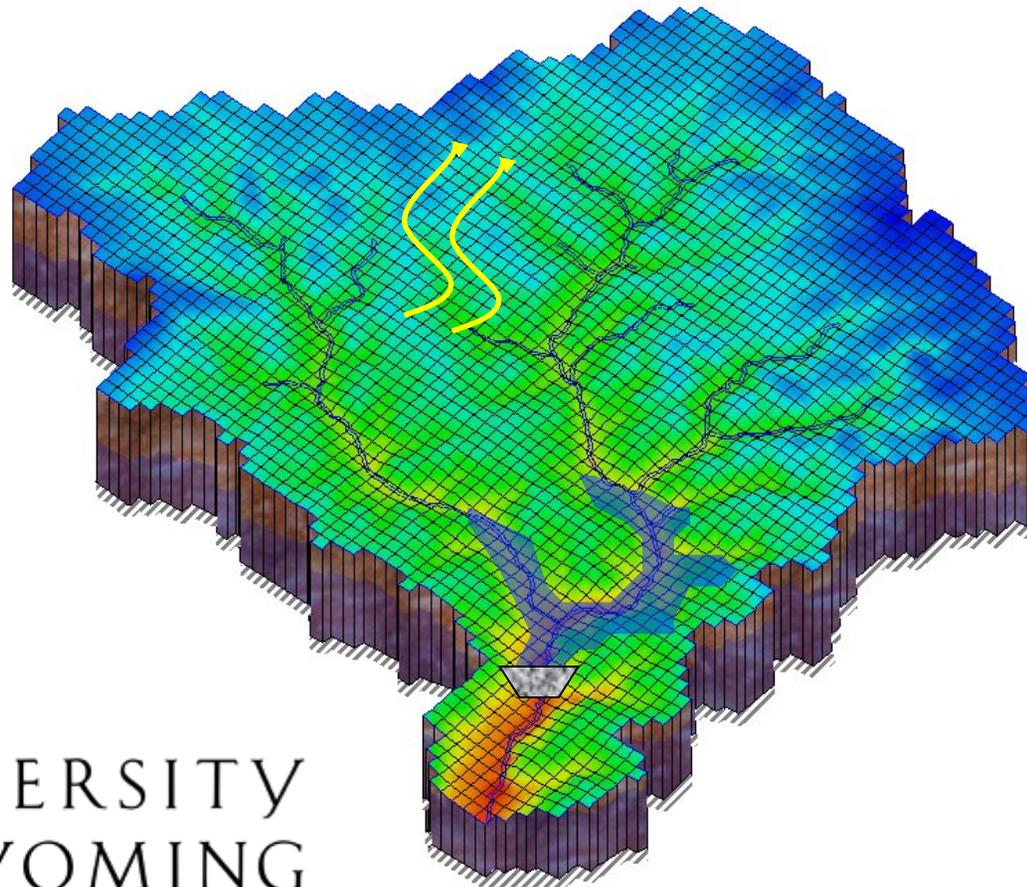

To consider the petascale in hydrology, one must think **BIG**.

Our Collaborators

- U.S. Army Corps of Engineers, Engineer Research and Development Center, Vicksburg, Mississippi, Coastal & Hydraulics and Information Technology Laboratories.
- National Center for Atmospheric Research, Research Applications Laboratory.

Gridded Surface/Subsurface Hydrologic Analysis (GSSHA) model

UNIVERSITY
OF WYOMING

New Thinking

GSSHA

- Square Grid
- Multi-solver
- Multi-physics
- 2D overland flow and groundwater flow
- 1D channel routing with hydraulic structures
- Richards or Green-Ampt Redistribution coupling between overland flow and groundwater
- Sediment/contaminant/nutrient transport

CI-WATER Project

- NSF Cyberinfrastructure Cooperative Agreement joint between Utah and Wyoming EPSCoR jurisdictions.
- Focused on acquisition of hardware, development of software, capacity building, education, and outreach.

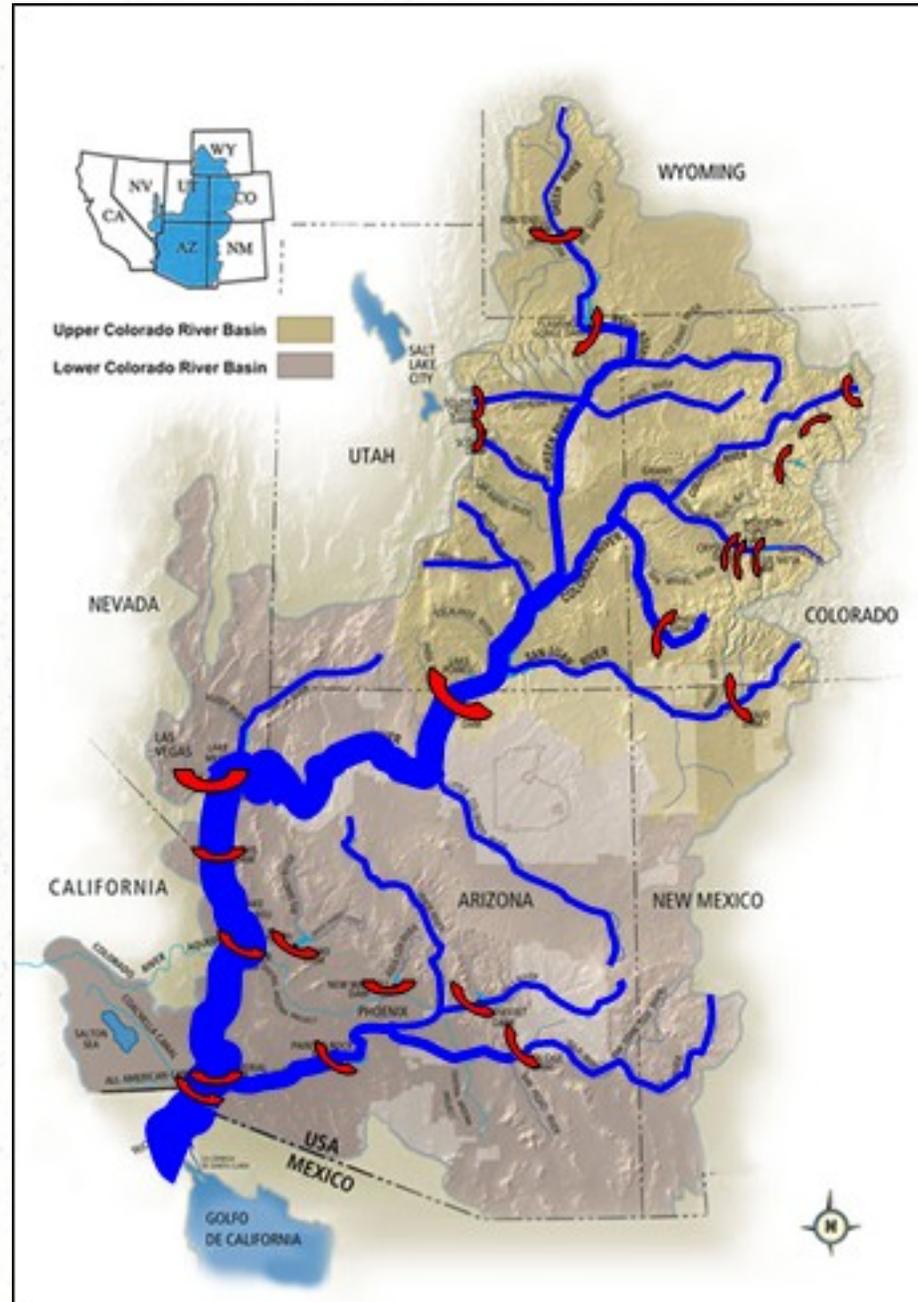

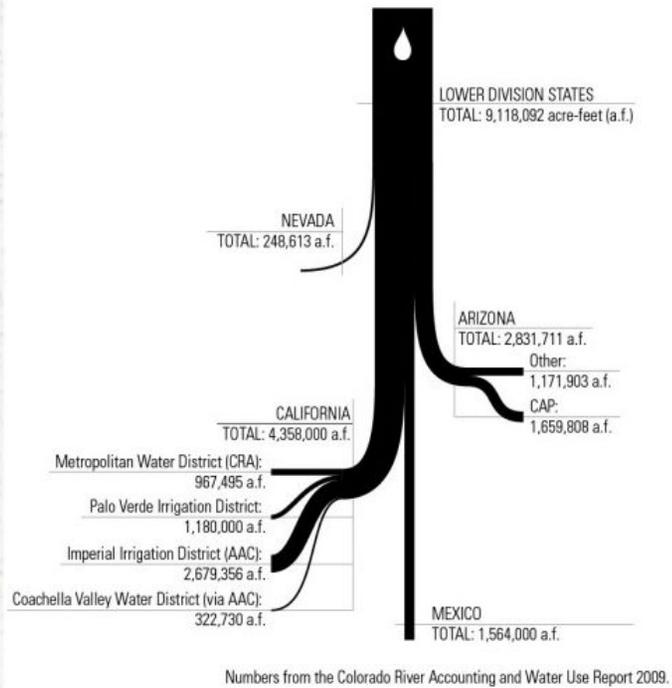

A big watershed problem:

- Upper Colorado River Basin: 280,000 km²
- High resolution important in mountains, where slope, aspect, vegetation, wind, drive snow redistribution, sublimation, and melt.
- Low resolution in broad and extensive basins, where interesting things seldom happen.
- *Square grid model structure is very inefficient for large watersheds where process scales vary.*

Colorado River Basin

Sources

Sinks

CI-WATER Component 3 Objective

Develop a high-resolution, large-scale hydrologic model to answer three questions:

- What are the potential impacts of climate change on the long-term yield of water from the upper Colorado River basin?
- How will future land-use changes due to development and natural causes such as fire, pine bark beetle affect water supplies?
- What are the effects of trans-basin diversions and increases in water consumptive use on the water storage in Lake Powell in 50 years?

Research Goals

- Increase accessibility of high performance computing to water resources researchers, engineers, and managers.
- Produce a set of modeling tools that allow consideration of future conditions in a modeling and probabilistic framework.
- Engage the wider community by releasing the code developed for research, development, and testing.

Establishing a Petascale Collaboratory for the Geosciences: Scientific Frontiers

- “A PCG will enable the simulation of the full spectrum of interactions among physical, chemical, and biological processes in coupled Earth system models.
- Land-atmosphere property fluxes are forced by surface ecosystem heterogeneity on scales of 1 m or less. The forcing is the result of a huge array of interacting biological, chemical, and geological processes
- Understanding the integrated effects of these processes is necessary for predicting ecosystem change and water availability.”

Law of the River, Colorado River Compact, 1922

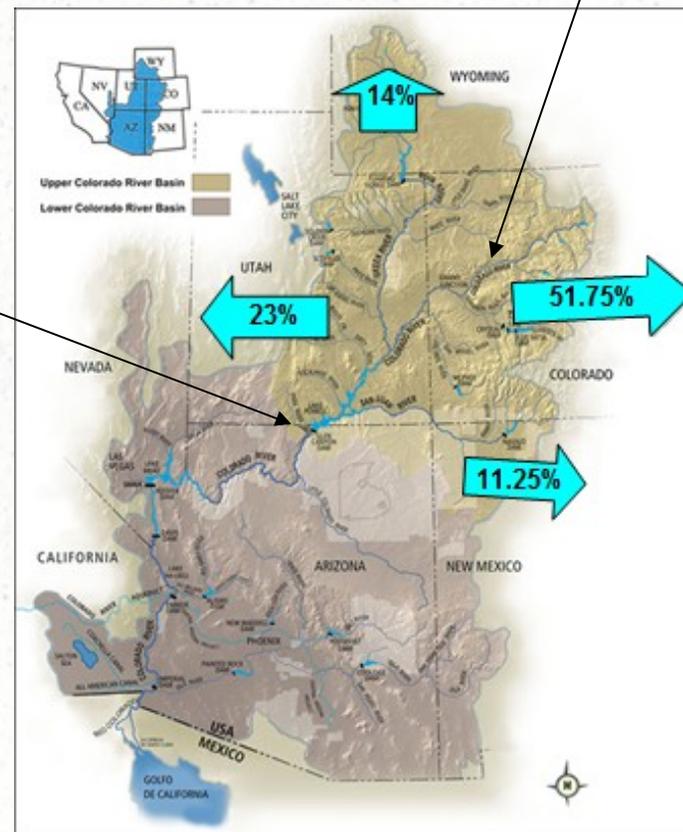

Lees Ferry, AZ, is the legal dividing point between Upper and Lower Basin

Lower Basin (CA, AZ, NV)
guaranteed 7.5 MAF/y

International: Mexico- 1.5 MAF/y

Note: 1 AF = 1.233 MI

Upper Basin (CO, UT, WY, NM),

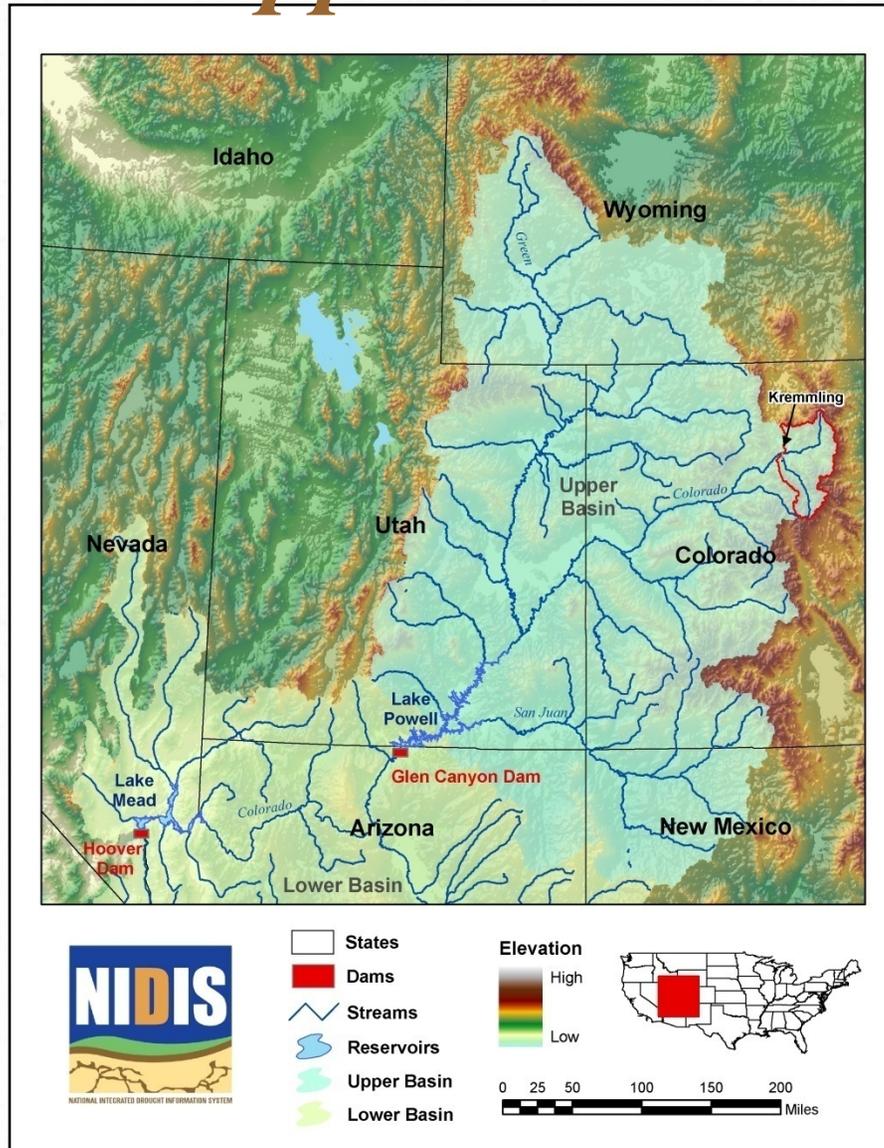

Glen Canyon Dam: The Upper States' bank account

- Pre-1963 average 12,963,000 AF
- Post-1963 average 10,701,000 AF

Upper Colorado River Basin

Basin Area: 288,000 km²

Streams: 467,000 km

Population: 400,000 (est)

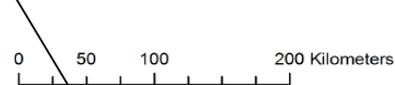

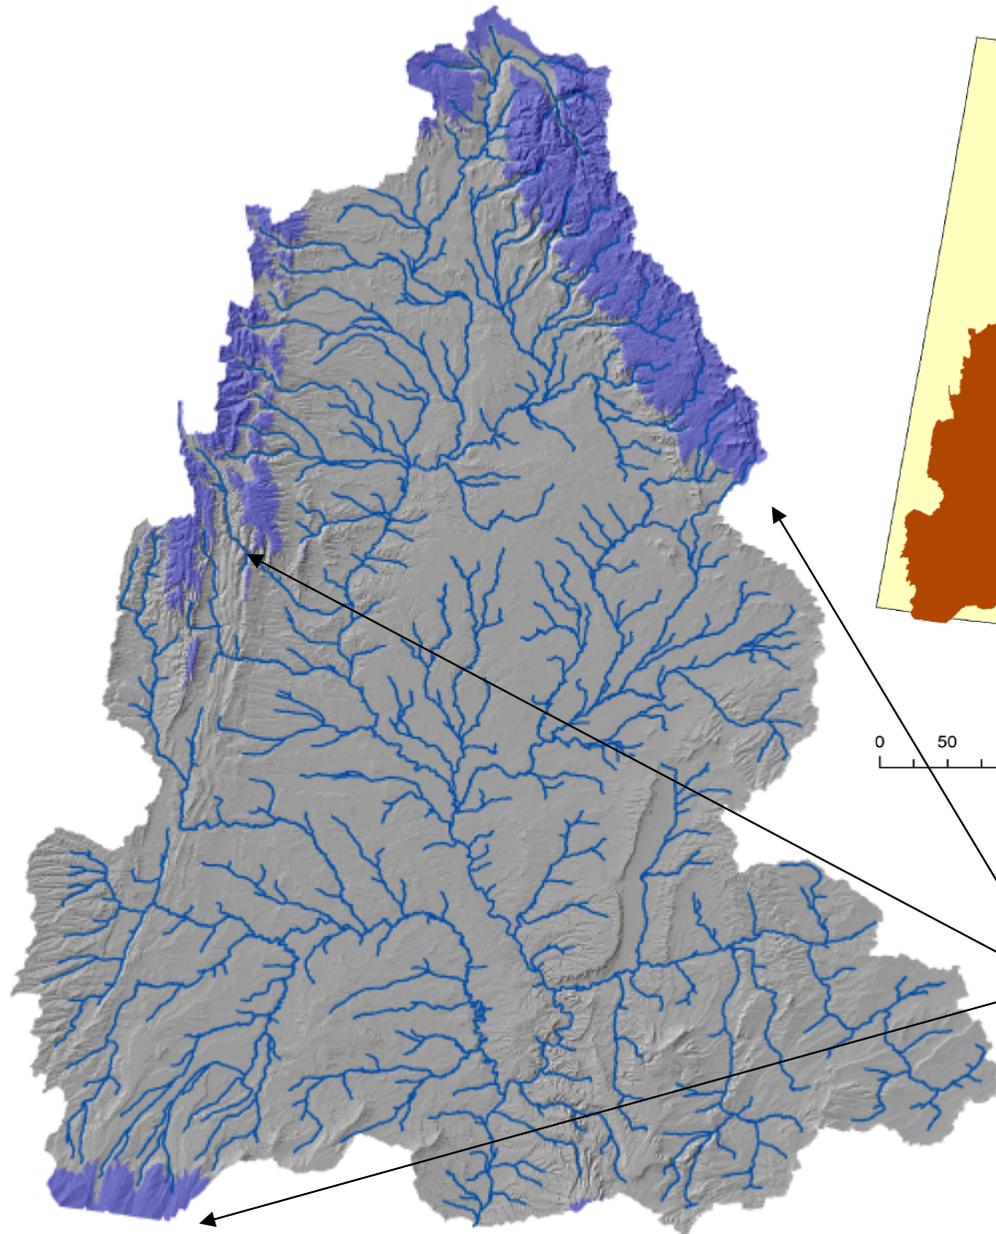

Area above 2700 m: 14.5%
(9,000 ft)

Area above 3050 m: 3.2%
(10,000 ft)

High Altitude Complexity

Test Area: Green River Basin in Wyoming

Darker blue areas are those above 2700 m elevation (9000 ft) where most snow melt occurs.

The NCAR-Wyoming Supercomputing Center (NWSC) provides dedicated *petascale* capabilities for geosciences.

For more information visit, www.nwsc.ucar.edu

NWSC Partners:

Architects, Contractors and Consultants:

H+L Architecture | Saunders Construction, Inc. | California Data Center Design Group | Rumsey Engineers | RMH Group
Martin & Martin Consulting Engineers | Rider Levett Bucknall | Reliable Resources | E Cube, Inc.

Wyoming's 20% Share of NWSC's **72,300** cores represents a huge increase in EPSCoR HPC capabilities...

- On the latest (6/11) Top500 list of fastest supercomputers, Wyoming's share on NWSC-1 alone is estimated to be...
 - The 28th fastest computer in the world
 - The 14th largest supercomputer in the US
 - The largest system in an EPSCoR state outside of Department of Energy facilities
 - The largest resource controlled by a university in the US

HPC Data Issues

- Data assimilation
 - How do we collect enough data to keep a Petascale computer busy? Just inventing data through interpolation is not acceptable.
 - In many sensor based applications today, there is a tsunami of data from each inexpensive sensor.
 - Satellite data comes 1-2 times per day in composite (incomplete) JPEG files. This is not necessarily high enough resolution and cloud cover can be a problem.
 - *We need a massive number of remote, on ground sensors, not just a massive quantity of data from a relatively few sensors.*
 - We need a symbiotic relationship between smart sensors and computational models, e.g., a dynamic data-driven application system, so that we get the right amount of data for the right scales while computing.
 - Finally, how do we afford massive data collection?

HPC Numerical Algorithms

- Multiscale methods
 - We use a base resolution with an average or median mesh size.
 - We can *upscale* to compute on a coarser mesh much quicker than on the base mesh.
 - We can *downscale* to compute on a finer mesh in a subregion of the entire domain to pick up features that are not visible on the base mesh. If the subregion is small enough, this is both computationally feasible and scientifically useful.
 - Dynamic steering of a computation is essential to make this work and can be done as postprocessing.
- Load balancing
 - This is a preprocessing step in the major computations.
 - First generate base meshes of interest and store them.
 - Generate a series of domain decompositions for different representative numbers of cores and store them.
 - Similar to the ocean modeling community meshes.

HPC Time Stepping

- Implicit methods
 - Implicit time stepping allows larger time steps while maintaining stability.
 - With massively parallel computers, an implicit method requires using massively parallel solvers from one time step to the next, while many common algorithms today just do not scale to $O(100K)$ cores, unfortunately.
- Explicit methods
 - Time steps usually limited by stability conditions to $\Delta t < C(\Delta x)^2$, where C is a positive real constant.
 - A new set of algorithms has recently been developed that are stable on given time steps, but use intermediate time steps (where stability may be violated) so that the stability condition is $\Delta t < C\Delta x$ instead (different C). Hence, vastly larger time steps possible.
 - Massively parallel computations are straightforward with explicit methods.

HPC Time Stepping

- Hybrid explicit-implicit methods
 - On the boundaries of the subregions use an explicit method to approximate the solution on the next time step.
 - Use an implicit method in each subregion, where the size of the subregions is small enough so that the algorithm used to get to the next time step scales well.
 - Possibly iterate on the boundary points to improve accuracy.
- Hybrid implicit-explicit methods
 - Downscale the problem to only the boundaries of the subregions and use an implicit method to approximate the solution on the next time step. This can be done in parallel based on subregions.
 - Use an explicit method in each subregion.
 - Possibly iterate on the boundary points to improve accuracy.
- Implications for Petascale computing
 - Both hybrid methods should scale and be fast.
 - Need to analyze which hybrid method works best for CI-WATER.

*We are not starting from scratch
(thanks to our collaborators)*

- USACE-ERDC providing:
 - finite element computational kernel derived from ADH model
 - Computational model builder (CMB)
 - ezVIZ HPC visualization tools
 - ezHPC user interface toolkit

Computational Model Builder

- Designed for **large complex domains & HPC**
- No licensing fees
- Cross platform
- User-configurable
- Built as several complimentary, independent tools

Making High Performance Computing Easy

Single Desktop Interface to Multiple HPC Systems

- Supports Novice to Expert Users
- Central Access to HPC Resources
- Custom Productivity Clients
- Complete Job Stream Management
- Fast Large File Transfers
- Secure Authentication

User Interface Toolkit – ezHPC

Tabbed Functions

- MOTD and system news @ HOME Tab
- Monitor Jobs & Queue Status on all machines

- Job Management
 - Script generator & editor
 - Allocation and Utilization viewer
- Fast large file transfers
- Easy access to custom scripts

Monitor Kerberos Ticket Session Time

Easy Access to on-line documentation

The screenshot displays the ezHPC v3.0 web interface. At the top, there's a navigation bar with tabs: Home, Monitor Jobs, Submit Jobs, Manage Files, Manage Scripts, Command Line, Help, and Logout. Below this is a 'Refresh' button and a message: 'Click 'Refresh' to get a job listing.' The main content area features a tabbed interface with machine names: BABBAGE, DAVINCI, EINSTEIN, FALCON, HAWK, JADE, MANA, MIDNIGHT, MJM, PINGO, and SAPPHIRE. The 'FALCON' tab is selected. Below the tabs, there are radio buttons for 'My Jobs', 'All Jobs', and 'Other Users' Jobs, and checkboxes for 'Running', 'Pending', and 'Completed'. A table lists job details with columns: User ID+, Job ID, Status, Wait Time, Start Time, Time Left, End Time, CPUs, Queue, and Sub Project. The table shows several jobs in 'RUN' status. Below the job list, there's a section titled 'Status of Queues on AFRL::FALCON' with a 'Threshold in Hours' set to 4. This section contains a table with columns: Queue, CPUs Running, CPUs Pending, Jobs Running, Jobs Pending, and CPUs Coming Available. The 'standard' queue shows 1454 CPUs running and 1 job pending.

User ID+	Job ID	Status	Wait Time	Start Time	Time Left	End Time	CPUs	Queue	Sub Project

Conclusions

- To get to Petascale, we need the following:
 - New ways of thinking about the hydrology model.
 - More complex and massive data collection through remote, intelligent sensors.
 - Multi-physics hydrologic process models at very fine scales.
 - Much more complex numerical algorithms in both time and space that are stable and new for O(100K) cores.
 - Much more complex software developed for O(1K) to O(10K) cores that is being extended to O(100K) to O(10M) cores.
 - By the time we are done getting to Petascale, Exascale will be threatening us.
 - This is not your daddy's hydrology or computing model anymore.
- Think BIG? Maybe MASSIVE is more appropriate.

Thank you
